## Questions on Guest Lectures

1. The Questions on Second Guest Lecture will be uploaded at LMS on Tuesday 12 September 2023 at folder “Assessment- Qs on Guest Lectures”
2. Question Upload time will be 5:30 pm on Tuesday, 12 September, 2023
3. Submission Deadline: 6:30 pm on Tuesday, 12 September, 2023 through Turnitin Submission at LMS link “Submissions”.
4. Maximum Similarity 10% ( don't copy the questions to keep the similarity down, just put the Question Number while answering)

# Smart Products

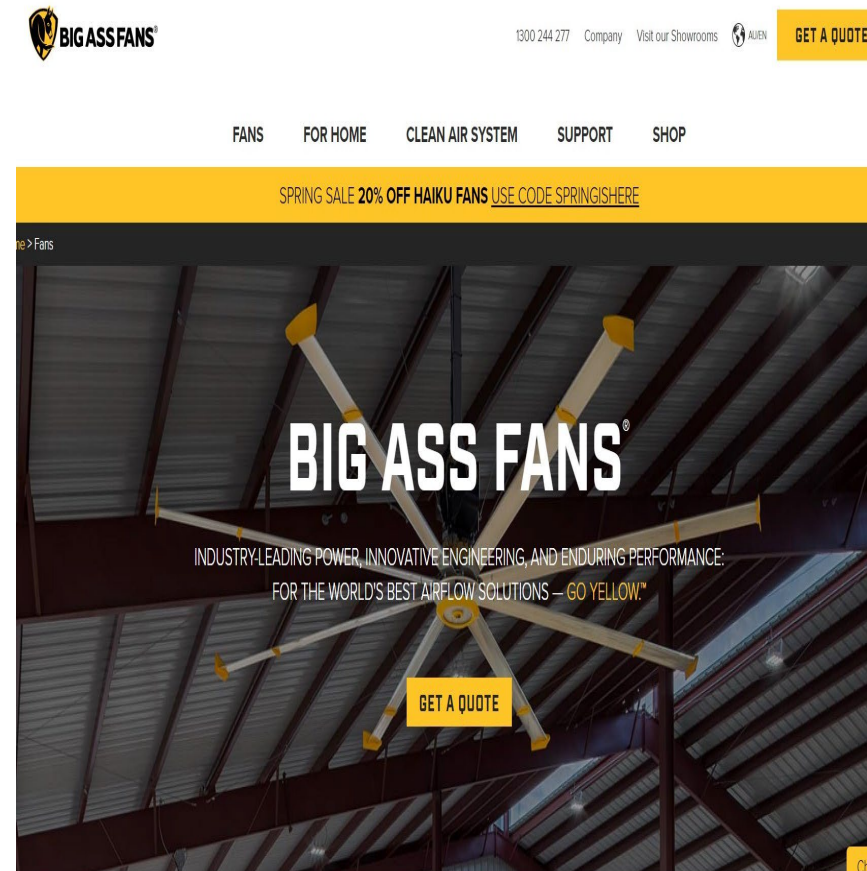

- In the energy sector, ABB's smart grid technology enables utilities to analyze huge amounts of real-time data across a wide range of generating, transforming, and distribution equipment (manufactured by ABB as well as others), such as:
  - Changes in the temperature of transformers and secondary substations.
- This alerts utility control centers to possible overload conditions, allowing adjustments that can prevent blackouts before they occur.

\*ABB (ASEA Brown Boveri) Ltd is a Swedish–Swiss multinational corporation headquartered in Zürich, Switzerland, operating mainly in robotics, power, heavy electrical equipment, and automation technology areas.

# Smart Products

In consumer goods, Big Ass ceiling fans sense and engage automatically:

- When a person enters a room
- Regulate speed on the basis of temperature and humidity
- Recognize individual user preferences and adjust accordingly.

# Smart Products : Tech Infrastructure

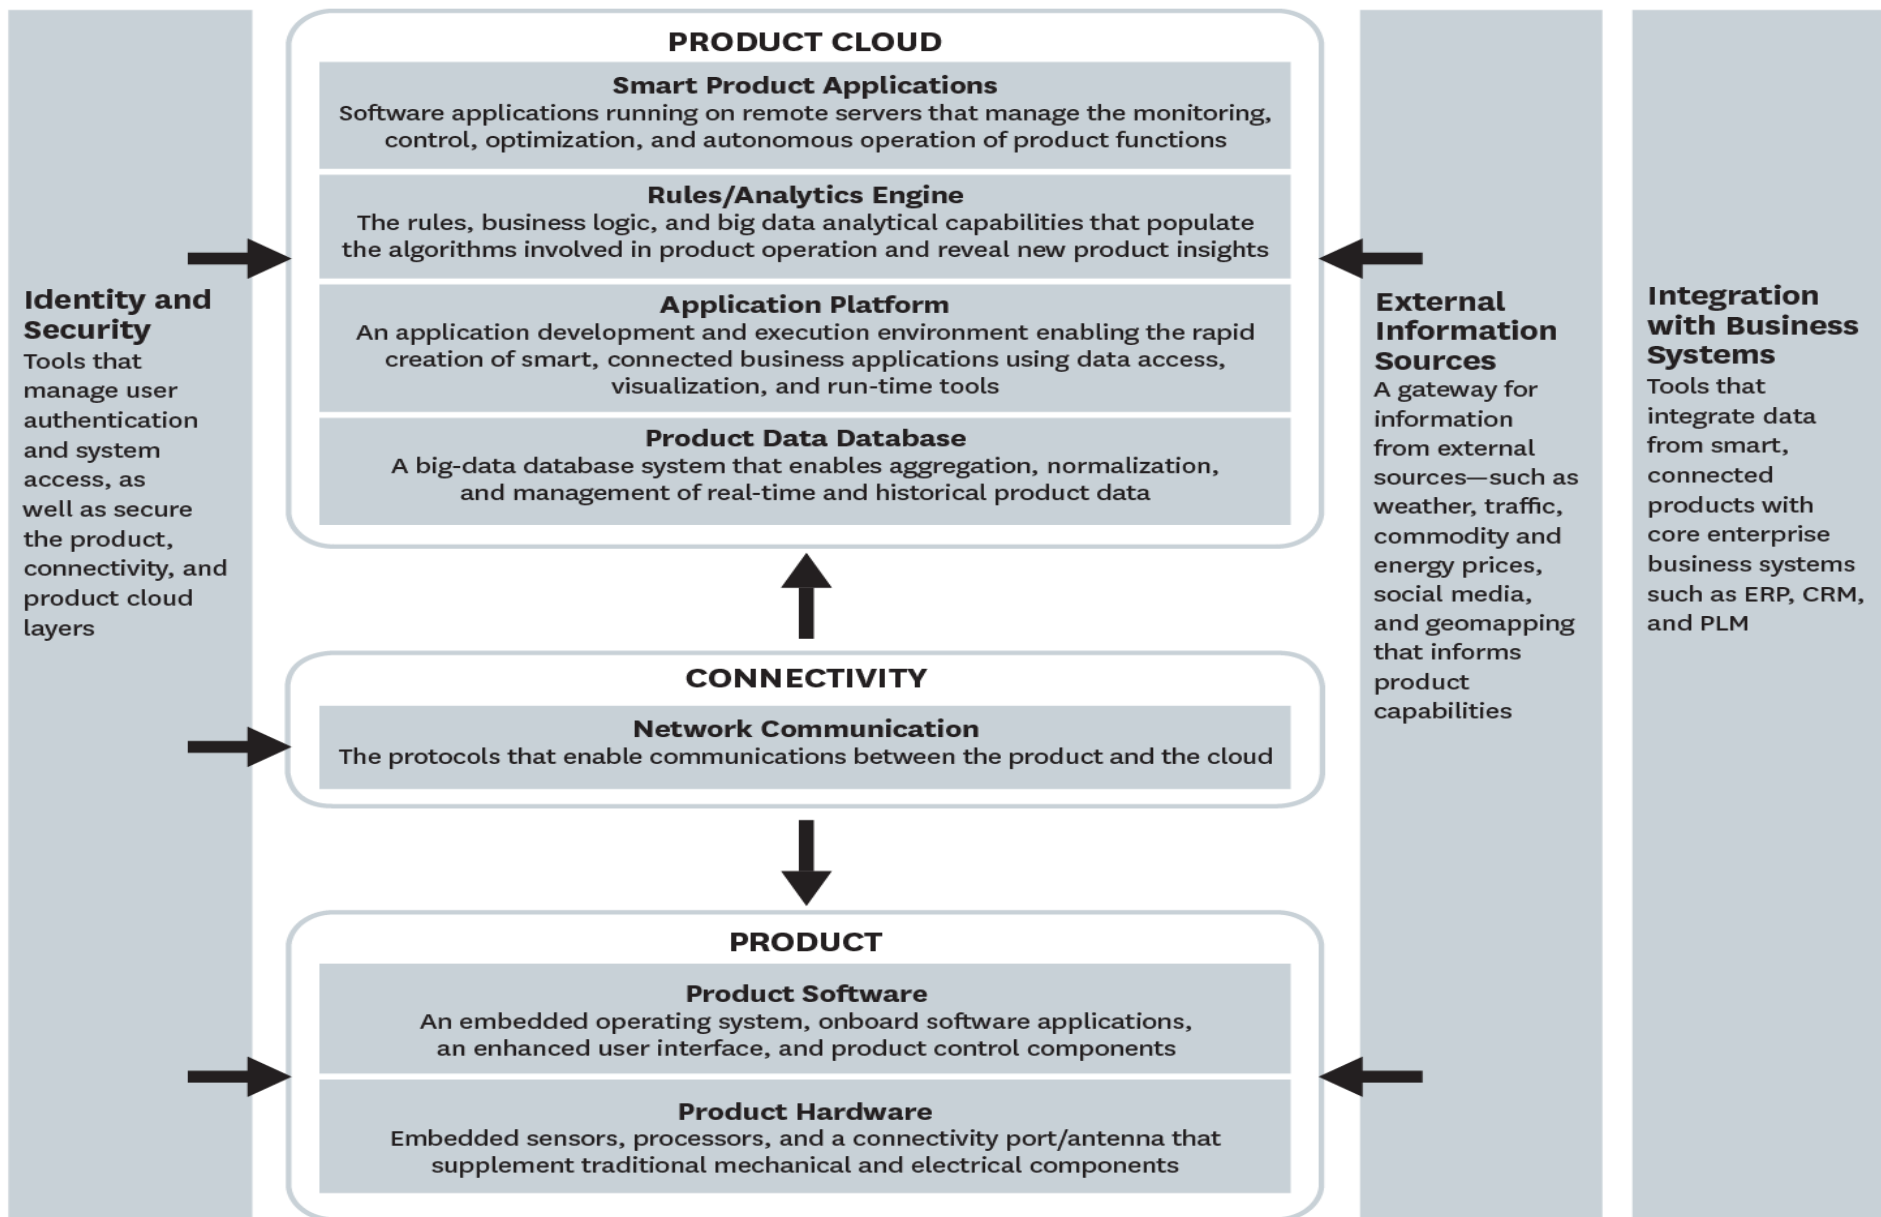

Smart, connected products require that companies build an entirely new **technology infrastructure**, consisting of a series of layers known as a “technology stack”.

# Smart Products : Tech Infrastructure

This technology stack includes :

- Modified hardware
- Software applications
- Operating system embedded in the product itself
- Network communications to support connectivity
- Product cloud (software running on the manufacturer's or a third-party server) containing the product-data database
- A platform for building software applications
- An analytics platform
- Smart product applications that are not embedded in the product

# Smart Products : Tech Infrastructure

All the layers are accessed through an identity and security structure, a gateway for accessing external data, and tools that connect the data from smart, connected products to other business systems. For example, ERP(Enterprise resource planning ), Product lifecycle management (PLM) and CRM (Customer relationship management) systems.

- ERP system track business resources (cash, raw material, production capacity, orders and payroll etc.
- PLM is the process of managing the entire life cycle of a product from its inception through the engineering, design, manufacture as well as service and disposal of manufactured products.
- CRM manages the company's relationship and interaction with customers and potential customers.

# Smart Products : Tech Infrastructure

- IoT enables not only rapid product application development and operation but the collection, analysis, and sharing of the potentially huge amounts of data generated inside and outside the products that has never been available before.
- Building and supporting the technology stack for smart, connected products requires substantial investment and a range of new skills—such as software development, systems engineering, data analytics, and online security expertise—that were rarely found in manufacturing companies in the past.

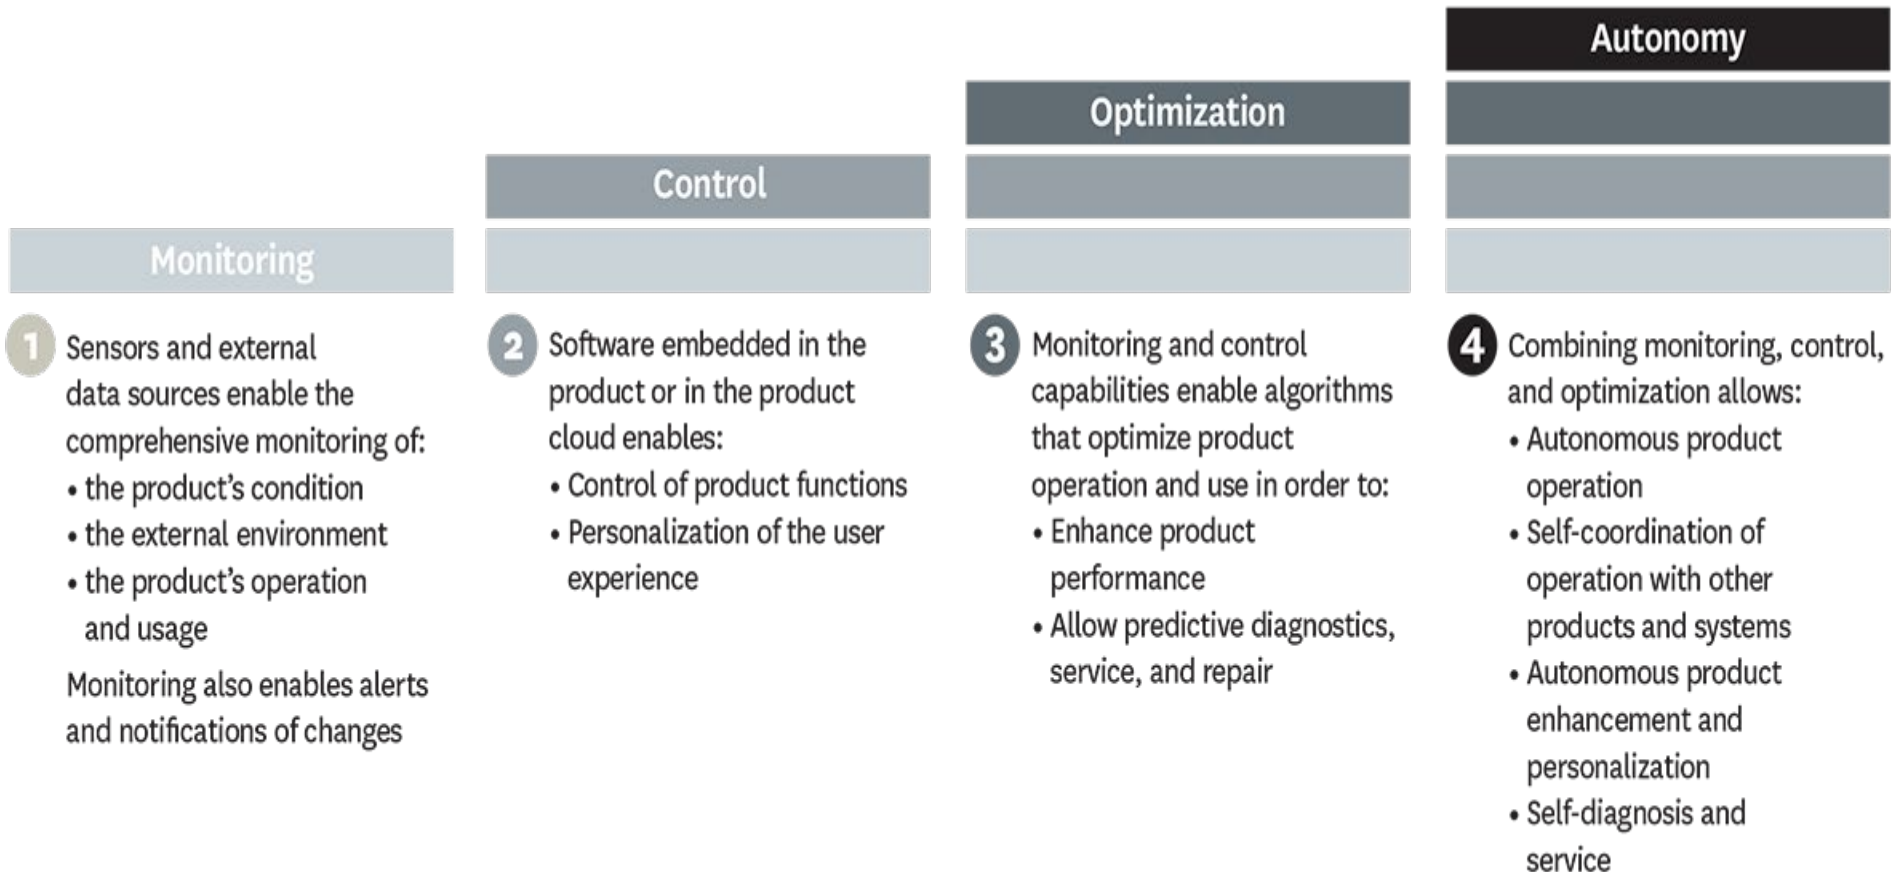

# Smart Products Capabilities Areas

# Capabilities of Smart Products

The capabilities of smart, connected products can be grouped into four areas:

- Monitoring
- Control
- Optimization
- Autonomy

# Capabilities of Smart Products

- Smart, connected products enable the comprehensive monitoring of a product's condition, operation, and external environment through sensors and external data sources.
- Using data, a product can alert users or others to changes in circumstances or performance.
- Monitoring also allows companies and customers to track a product's operating characteristics and history and to better understand how the product is actually used.

# Monitoring

- The collected data has important implications for design (by reducing over-engineering), market segmentation (through the analysis of usage patterns by customer type), and after-sale service (by allowing the dispatch of the right technician with the right part, thus improving the fix rate).
- Monitoring data may also reveal warranty compliance issues as well as new sales opportunities, such as the need for additional product capacity because of high utilization.

- In some cases, such as medical devices, monitoring is the core element of value creation.
- *Medtronic's* digital blood-glucose meter uses a sensor inserted under the patient's skin to measure glucose levels in tissue fluid and connects wirelessly to a device that alerts patients and clinicians up to 30 minutes before a patient reaches a threshold blood-glucose level, enabling appropriate therapy adjustments.

- Monitoring capabilities can span multiple products across distances.
- Joy Global, a leading mining equipment manufacturer, monitors operating conditions, safety parameters, and predictive service indicators for entire fleets of equipment far underground.
- Joy Global also monitors operating parameters across multiple mines in different countries for benchmarking purposes.

- Smart, connected products can be controlled through remote commands or algorithms that are built into the device or reside in the product cloud.
- For example, “if pressure gets too high, shut off the valve” or “when traffic in a parking garage reaches a certain level, turn the overhead lighting on or off, or display the filled capacity”.

- Control through software embedded in the product or the cloud allows the customization of product performance to a degree that previously was not cost effective or often even possible.
- The same technology also enables users to control and personalize their interaction with the product in many new ways. For example, users can adjust their Philips Lighting hue lightbulbs via smartphone, turning them on and off, programming them to blink red if an intruder is detected, or dimming them slowly at night.
- Doorbot (now named as **Ring**, <https://ring.com>), a smart, connected doorbell and lock, allows customers to give visitors access to the home remotely after screening them on their smartphones.

- The rich flow of monitoring data from smart, connected products, coupled with the capacity to control product operation, allows companies to optimize product performance in numerous ways, many of which have not been previously possible.
- Smart, connected products can apply algorithms and analytics to dramatically improve output, utilization, and efficiency.

- In wind turbines, for instance, a local microcontroller can adjust each blade on every revolution to capture maximum wind energy. And each turbine can be adjusted to not only improve its performance but minimize its impact on the efficiency of those nearby.
- Real-time monitoring data on product condition and product control capability enables firms to optimize service by performing preventative maintenance.
- Advance information about what is broken, what parts are needed, how to accomplish the fix reduces the repair costs.

- Monitoring, control, and optimization capabilities combine to allow smart, connected products to achieve a previously unattainable level of autonomy.
- At the simplest level is autonomous product operation like that of the iRobot Roomba, a vacuum cleaner that uses sensors and software to scan and clean floors in rooms with different layouts.
- More-sophisticated products are able to learn about their environment, self-diagnose their own service needs, and adapt to users' preferences.

- Autonomy not only can reduce the need for operators but can improve safety in dangerous environments and facilitate operation in remote locations.
- Autonomous products can also act in coordination with other products and systems. For example, the energy efficiency of the electric grid increases as more smart meters are connected, allowing the utility to gain insight into and respond to demand patterns over time.

- Ultimately, products can function with complete autonomy, applying algorithms that utilize data about their performance and their environment—including the activity of other products in the system—and leveraging their ability to communicate with other products.
- Example, The Google self-driving car project , Waymo.
